Article published on 31 March 2011

We present a summary of the main findings of the latest report of the European Food Safety Authority and European Centre for Disease Prevention and Control on zoonoses, zoonotic agents and food-borne outbreaks in the European Union (EU), based on data from 2009. Zoonoses are prevalent and widely distributed across several countries in the EU. The most important highlight of this report was the continuous decrease of human salmonellosis since 2005, probably due to effective control programmes in livestock.

Background

The European Union summary report on trends and sources of zoonoses, zoonotic agents and food-borne outbreaks in 2009, produced by the European Food Safety Authority (EFSA) and the European Centre for Disease Prevention and Control (ECDC) on 22 March 2011, describes the five-year trends (2005–2009) and occurrence of zoonotic infections and agents in humans, animals and foodstuffs in the 27 European Union (EU) Member States. Reported cases from countries of the European Economic Area (EEA)/ European Free Trade Association (EFTA), namely Iceland, Liechtenstein, Norway and Switzerland [1] are also included in the preliminary description but not in further analysis or trends.

Zoonoses are diseases that are transmissible between animals and humans. Humans can acquire these infections directly from contact with sick or carrier animals, or through the ingestion of contaminated foodstuffs or from other environmental sources. The severity of these diseases in humans can vary from mild symptoms to chronic sequelae or life-threatening conditions.

In order to prevent zoonoses from occurring in humans and to control such diseases, it is important to identify which animals and foodstuffs are the main sources of the infections. Thorough analysis and description of the distribution of zoonotic diseases among EU countries allows targeting of control measures and monitoring of the progress of food-safety policies in the EU. The annual EU summary report compiles information

from human surveillance systems and from monitoring programmes for food and animals, with the aim of protecting human and animal health according to the Zoonoses Directive 2003/99/EC [2].

Assisted by the Zoonoses Collaboration Centre-Technical University of Denmark (ZCC-DTU), EFSA and ECDC jointly analysed the data and a summary of the main findings are presented in this article.

Trends in the main zoonoses and zoonotic agents Campylobacteriosis

In 2009, as in the previous four years, campylobacteriosis was the most commonly reported zoonotic disease in humans (198,252 confirmed cases). There was a 4% increase in the number of reported cases compared with 2008. The notification rate was 45.6 cases per 100,000 population, with children aged under five years having the highest notification rate (128 cases per 100,000 population). The number of reports of human campylobacteriosis was stable over the five-year period, but the incidence was always higher during the summer months. This could be due to a seasonal effect that has not been addressed through traditional *Campylobacter* control programmes for food and animals.

In foodstuffs, as in previous years, *Campylobacter* was most commonly isolated from fresh broiler meat at different stages of production: 31% of samples (n=7,312) were positive. According to the recent scientific opinion of EFSA biological hazards panel, about 20–30% of human campylobacteriosis cases can be attributed to the consumption and handling of chicken meat [3]. In pig meat samples, *Campylobacter* was detected much less frequently (0.6%, n=1,006) than in broiler meat. However, there was high variability in the number of reporting countries and sample size, depending on animal species and type of meat.

C. jejuni was the most frequently reported species in humans as well as in poultry and cattle, while *C. coli*

was less prevalent in humans and was isolated mainly from pigs.

Salmonellosis

Salmonellosis was the second most commonly reported zoonotic infection in humans in 2009, with 108,614 confirmed cases reported and a notification rate of 23.7 cases per 100,000 population, which is 17% less than in 2008. There has been a statistically significant decreasing trend in the notification rate during 2005 to 2009, with a mean reduction of 12% per year. The decrease has been particularly sharp for the most commonly reported serovar in humans, *Salmonella* Enteritidis: notifications fell by 24% from 2008 to 2009. The second most common serovar, *S. Typhimurium*, was also reported less frequently in 2009 compared with 2008, presenting a decrease of 10%.

In food, *Salmonella* was the most commonly identified pathogen in fresh poultry and fresh pork meat, where 8.7% (n=30,544) and 0.7% (n=83,797) of samples were found positive, respectively. The bacterium was rarely detected in vegetables, fruit or dairy products.

Harmonized *Salmonella* EU control programmes in poultry have been implemented progressively since 1994, starting with primary production. In 2009, Member States had to meet the EU reduction target of having $\leq 1\%$ of breeding flocks of *Gallus gallus* (chickens) infected with the five target serovars (*S. Enteritidis*, *S. Typhimurium*, *S. Hadar*, *S. Infantis* and *S. Virchow*) [4,5]. Control efforts at poultry-farm level in Member States are considered to have contributed remarkably to a positive public-health effect in reducing the number of reported human salmonellosis cases.

It is reassuring that the declining trend of human salmonellosis continued in 2009. This is likely to be the result of intensified control programmes of *Salmonella* in animal reservoirs, particularly in poultry, and better hygiene practices throughout the food production chain. The introduction of molecular surveillance at the EU level in the future will provide more clues about the importance of different animal and food sources of infection and the impact of *Salmonella* control programmes in livestock.

Yersiniosis

The number of reported human cases of yersiniosis in 2009 was 7,595, with a notification rate of 1.65 cases per 100,000 population. Although the notification rate decreased significantly ($p < 0.01$) since 2005 (2.6 cases per 100,000 population), the disease continues to be the third most frequently reported zoonosis in the EU.

In animals, *Yersinia* spp. were reported mainly in pigs and pork products. *Yersinia enterocolitica* was isolated from 4.8% of pork samples (n=2,134).

Listeriosis

In 2009, the notification rate of human listeriosis was 0.36 cases per 100,000 population. The number of confirmed cases increased by 19% in 2009 (n=1,645) compared with 2008 (n=1,381). Listeriosis is an important food-borne disease due to its severity: it can lead to a high risk of abortion in pregnant women and high levels of mortality in elderly people (a case fatality rate of 19% was reported in people aged 65 years and over). The highest notification rate was also reported in this age group (1.1 cases per 100,000 population), representing 59% of all reported cases. Only 4.2% of the reported cases were detected among children aged under five years.

Foodstuffs that are considered the main source of *Listeria* in the EU include ready-to-eat (RTE) products (fish and meat) and soft cheeses. According to the EU microbiological criteria, foodstuffs that contain less than 100 colony-forming units (cfu)/g of *L. monocytogenes* at the retail level are considered acceptable for human consumption [6]. In 2009, the highest proportions of non-compliant food products at retail level were found in RTE fish products, cheese (especially soft and semi-soft) and RTE products of meat origin, although the level was lower than in the previous two years.

The high proportion of deaths among elderly people as a result of *Listeria* infection is of particular concern. An EFSA-ECDC collaboration on typing of *Listeria* in RTE products and clinical cases of human listeriosis started in 2010 and continues to 2012. The results provided by this study will contribute to a better understanding of listeriosis epidemiology in the EU and should help to target effective control and preventive measures within both food safety and public health.

Verotoxigenic *Escherichia coli* (VTEC) infection

A total of 3,573 confirmed human cases of verotoxigenic *E. coli* (VTEC) infection (0.75 cases per 100,000 population) were reported in 2009, a 13% increase compared with 2008 (n=3,159). The notification rate has increased since 2007 (0.6 cases per 100,000 population). VTEC O157 was again the serotype most commonly reported, although VTEC isolates were not characterised at the serotype level in 28% of the cases in 2009. As in previous years, the notification rate was highest in children aged 0–4 years. A considerable increase (of 66%) in the number of reported cases who developed haemolytic uremic syndrome was detected in 2009 (n=242) compared with 2008 (n=146), occurring mainly among 0–4 year-olds. Several outbreaks of VTEC infection were detected in United Kingdom and the Netherlands in 2009 and have contributed to the increasing trend in Europe and increased the number of haemolytic uremic syndrome cases [7-9]

In animals, VTEC was mainly isolated from cattle and, to a lesser extent, from small ruminants such as sheep and goats. In food, VTEC was detected mainly in meat

from ruminants: 3.2% (n=248) of sheep meat samples, followed by 2.3% (n=9,285) of bovine meat samples. It was also isolated from raw cow's milk. The reported occurrence of VTEC bacteria in food was generally low, and the levels have been relatively constant between 2005 and 2009.

Q fever

A total of 1,987 confirmed human cases of Q fever were reported in 2009, representing a 25% increase compared with 2008 (n=1,594). However, the majority of cases (91%) was detected in two countries: the Netherlands (n=1,623) and Germany (n=190). Adults aged 45–64 years had the highest notification rate (1.2 cases per 100,000 population).

The continued increase in Q fever in 2009 was the result of several outbreaks in which people were exposed to infected sheep and goats, mainly in the Netherlands.

Trends in zoonotic parasitic diseases and zoonotic parasites

Trichinellosis

Reported cases of human trichinellosis increased by 12% in 2009 (n=748) compared with 2008 (n= 670). The distribution of reported cases was not homogeneous across EU Member States, as the majority of cases (94%) was reported by four eastern European countries (Bulgaria, Romania, Poland and Lithuania). The reason for this large proportion of human cases in these countries may be linked to particular regional habits, such as raising pigs in backyards for private consumption, for which official meat inspection for the presence of *Trichinella* spp. is not carried out.

The increased number of cases of trichinellosis in these countries is of major concern because the disease is easily preventable when appropriate veterinary meat inspection is carried out and preventive measures are taken.

Echinococcosis

There were 790 reported human cases of echinococcosis in 2009, which is 11% fewer than in 2008 (n=891). Among reported cases with a known species, the predominant species was still *E. granulosus* (77%) while *E. multilocularis* was reported three times less frequently.

In animal populations, 18 Member States submitted data on *Echinococcus* spp. found in domestic livestock (cattle, pigs, sheep, goats and solipeds) as part of routine screening at slaughter. In addition, 10 Member States reported data on foxes positive for *E. multilocularis* (15.6% of tested foxes carried this species). Control measures implemented for dogs, such as deworming treatment, can restrict the spread of echinococcosis. However, foxes remain a potential source of exposure and vehicle for spread in some EU countries.

Toxoplasmosis

In 2009, a total of 1,259 confirmed human cases of toxoplasmosis were reported. The highest proportion was recorded in women aged 24–44 years, probably due to routine screening for antibodies against *Toxoplasma* during pregnancy.

Sheep and goats were the animal species with the highest proportion of *Toxoplasma*-positive samples reported (24.4%, n=4,217).

Trends in other zoonoses: brucellosis, tuberculosis due to *Mycobacterium bovis* and rabies

In 2009, human cases of brucellosis (n=401) decreased by 35.2% compared with 2008 (n=619). The number of cases has been decreasing significantly ($p < 0.01$) in the EU since 2005.

Cases of human tuberculosis due to *Mycobacterium bovis* in 2009 were not reported to the European Surveillance System (TESSy) at the time of the report production. Therefore the trends and epidemiological analysis were based on 2008 data. The number of confirmed human cases of tuberculosis due to *M. bovis* increased in the EU by 7.5% in 2008 (n=115) compared with 2007 (n=108). However, this could be a normal variation in the disease occurrence. Overall, the numbers of human cases decreased during the previous four years, mainly due to effective disease eradication programmes implemented by Member States in cattle herds.

In 2009, one indigenous case of rabies – in a woman bitten by a rabid fox – was reported in Romania. This is the second autochthonous case of rabies that occurred in Romania in the previous two years.

Conclusion

In 2009, campylobacteriosis, salmonellosis and yersiniosis were the most commonly reported zoonotic infections in humans of those monitored for this report in the EU, as in previous years. Parasitic zoonoses – trichinellosis, echinococcosis and toxoplasmosis – are still present in the EU. While some diseases, such as salmonellosis, have continued to decline, probably due to effective EU control measures in animal reservoirs, others have increased considerably, such as trichinellosis, even though the disease can be easily prevented.

The results of this report highlight the importance of close collaboration between veterinarians and public health specialists and the need for robust surveillance systems, in the animal/food sector and in humans, in order to monitor the impact of EU-wide control measures, detect emerging trends and sources and unexpected changes in the disease dynamics of zoonoses in Europe.
