The *mcr-1* gene was found in 11 isolates from a Portuguese *Salmonella* collection (n = 1,010; 58 serotypes; 2002–15) of clinical samples, foodstuff, food-animals and water. *Mcr-1* has been located on different plasmids (IncX4/IncHI2) in pig-associated multidrug-resistant, copper-tolerant S.1,4,[5],12:i:-/ST34 and S. Rissen/ST469 clones from human and pork products since at least 2011. Our data highlight dissemination of *mcr-1* by successful resistant clones in Europe and raise questions about the efficacy of copper-based interventions to reduce colistin use.

Since the description of plasmid-mediated colistin resistance encoded by the *mcr-1* gene in Enterobacteriaceae from multiple sources in China [1] and its worldwide dissemination mostly in animal sources [2], the use of polymyxins (colistin) in food-producing animals has been questioned in Europe because it may have an impact on human health [3]. Nevertheless, data on the transmission of *mcr-1*-mediated colistin resistance particularly by clonal expansion are lacking [3,4]. In fact, the *mcr-1* gene has been found in zoonotic food-borne bacteria such as *Salmonella* [2] but the presence of this gene in particular successful resistant clones has not been demonstrated [3]. In this study, we report the presence of the *mcr-1* gene in pig-associated clinically relevant *Salmonella* serotypes and clones recovered from human clinical samples and pork products in Portugal, collected as early as 2011.

**Laboratory investigation**

We analysed a total of 1,010 *Salmonella* isolates of 58 serotypes from several sources (human clinical cases, food products, food-animal production settings and aquatic environments) and regions of Portugal, collected between 2002 and 2015 (Table 1). The isolates were screened for the *mcr-1* gene by PCR and sequencing, using primers CLR5-F (5´-CGGTCAGTCCGTTTGTTC-3´) [1] and Mcr1-Rv2 (5´-CCAGCGTATCCACGCTTCTTT-3´) [this study].

The 1,010 isolates comprised the most frequent worldwide *Salmonella* serotypes (n = 256 S. Typhimurium and n = 34 S. Enteritidis), but also emerging serotypes (n = 436 S. 1,4,[5],12:i:- and n = 93 S. Rissen) or serotypes less frequently detected in European surveillance studies (n = 191 isolates from 54 different serotypes). They included all isolates previously characterised [5,6] and recent ones from ongoing surveillance studies (data not shown) covering all serotypes, sampling dates, sources, regions, antibiotic susceptibility phenotypes/genotypes and PFGE types. The isolates positive for *mcr-1* by PCR were further tested for susceptibility to colistin by the proposed broth microdilution method [7] and interpreted according to the European Committee on Antimicrobial Susceptibility Testing [8]. Isolates were also subjected to standard conjugation assays using the recipient strain *Escherichia coli* HB101 [6]. Replicon typing, pMLST, hybridisation experiments (I-CeuI/S1-PFGE nuclease) [5,9] and detection of the insertion sequence element IS481 was performed in *Salmonella* strains and transconjugants. The presence and location of IS481 was determined using primers IS481-Fw (5´-GTCGCTTTGGACATTGGGAA-3´) and IS481-Rv (5´-GATTGATGTCTTGGTGCTTCGG-3´) designed as part of this study, and CLR5-R (5´-CTTGGTCCGTTCTGTAAGG-3´) [1]. Clonal relatedness of *Salmonella* strains was assessed by XbaI PFGE [5,6] and MLST [10].

**Detection of mcr-1 gene in pig-associated clinically-relevant clones**

The *mcr-1* gene was detected in 11 (1.1%) of the 1,010 Portuguese *Salmonella* isolates, recovered from human clinical sources and pork food products from across the country (Table 1, Table 2). This gene had 100% homology with the first published *mcr-1* sequence in an

The serotypes of $S$. isolates are presented only for those among which $mcr$-1-positive ones were detected.

Other studied food products comprised: poultry, beef, cow, quail, clam and cooked meals.

During the study period (2002 to 2015), $S$. isolates harbouring the $mcr$-1 gene were only recovered between 2003 and 2015 and originated from human clinical sources (0.8%, n = 95/12,711) and pork products, mostly from slaughterhouses (2.4%, n = 526) (Table 1). Colistine has been widely used in veterinary medicine, primarily in food-producing animals, primarily in pigs [16,17]. The available data from 2004 to 2006 had already showed high use of colistine for food-producing animals in Portugal [18], which is one of the European countries with highest consumption of polymyxins that has been increasing in the last years (2011–13) [3,19]. Taking into account the current picture of colistine use in Portugal, the detection of $mcr$-1 in the most recent collections and in pork products is of concern. Nevertheless, data on chronology, current prevalence of the $mcr$-1 gene and its evolution in bacteria from animals, food and humans are lacking [3].

The 11 $mcr$-1-positive $S$. isolates belonged to the serotypes $S$. 1,4,[5],12:i:- and $S$. Rissen (Table 2), which have been strongly associated with pig production and caused human infections in Europe [5,6,20-22] including in Portugal [23]. In both cases, we found them associated with particular successful

multidrug-resistant (MDR) clonal lineages, either of the $S$. Rissen/ST469 clone or the $S$. 1,4,[5],12:i:-/ST34 European clone that is currently spreading epidemiologically in European countries [5,20,22] and has been dominant in our $S$. collection for the last years [5,6,20; unpublished data]. A previous report on $mcr$-1 in the clinically relevant $S$. Typhimurium/ST34 was associated with travel to South-East Asia [13].

Of note, all $S$. 1,4,[5],12:i:- and $S$. Rissen $mcr$-1-carrying isolates were co-resistant to antibiotics used in a human and/or veterinary context and carried diverse metal tolerance genes, remarkably those conferring tolerance to copper (all carrying pcoD4-silA on the chromosome) (Table 2), a feed additive mostly used for pigs or piglets in Europe. The fact that these successful clones presented higher tolerance to copper, as previously demonstrated [6,20], can contribute to their selection and wider expansion with potential repercussions for $mcr$-1 transmission.

Location of $mcr$-1 gene in diverse plasmid backbones

The $mcr$-1 gene was located on two plasmid types, IncX4 (n = 5; 35 kb; 4 transferable) and IncHI2 (n = 6), either of ST4 subtype (n = 3; 200–300 kb; all transferable) or non-typeable (n = 3; 120–125 kb; all non-transferable) and mostly associated with the ISAp1 transposable element (Table 2). IncHI2/ST4 and IncX4 plasmids have been widely implicated in the spread of $mcr$-1 gene in diverse $S$. serotypes and other Enterobacteriaceae in European and non-European countries, both from human and animal sources [2,12-

14]. Transferability of the $mcr$-1 gene was achieved from $S$. Rissen (n = 1) and $S$. 1,4,[5],12:i:- (n = 6) isolates and was associated with a 32–64-fold increase in the colistine MIC and, in some isolates, with acquisition of

Escherichia coli strain from China (GenBank accession number: KP347127) [1], which was further described in diverse other Enterobacteriaceae including sporadic $S$. isolates from European countries (France, the Netherlands, Spain, the United Kingdom) [2,11-14]. In most of these studies, detection of $mcr$-1 gene was only performed in colistine-resistant isolates. This impairs the determination of its real prevalence because the gene may be silent, as described in one $E$. coli strain [15]. All our isolates carrying the $mcr$-1 gene presented a minimum inhibitory concentration (MIC) of 4–8 mg/L for resistance to colistine (Table 2).

During the study period (2002 to 2015), $S$. isolates harbouring the $mcr$-1 gene were only recovered between 2003 and 2015 and originated from human clinical sources (0.8%, n = 95/12,711) and pork products, mostly from slaughterhouses, (2.4%, n = 526) (Table 1). Colistine has been widely used in veterinary medicine, primarily in food-producing animals, primarily in pigs [16,17]. The available data from 2004 to 2006 had already showed high use of colistine for food-producing animals in Portugal [18], which is one of the European countries with highest consumption of polymyxins that has been increasing in the last years (2011–13) [3,19]. Taking into account the current picture of colistine use in Portugal, the detection of $mcr$-1 in the most recent collections and in pork products is of concern. Nevertheless, data on chronology, current prevalence of the $mcr$-1 gene and its evolution in bacteria from animals, food and humans are lacking [3].

The 11 $mcr$-1-positive $S$. isolates belonged to the serotypes $S$. 1,4,[5],12:i:- and $S$. Rissen (Table 2), which have been strongly associated with pig production and caused human infections in Europe [5,6,20-22] including in Portugal [23]. In both cases, we found them associated with particular successful

AMP: ampicillin; CIP: ciprofloxacin; CLO: chloramphenicol; GEN: gentamicin; MIC: minimum inhibitory concentration; PEF: pefloxacin; pMLST: plasmid multilocus sequence type; STR: streptomycin; SUL: sulfamethoxazole; TET: tetracycline; TMP: trimethoprim.

* The serotypes of *Salmonella* isolates were determined by classical serotyping, performed at the National Centre of Salmonella (INSA, Lisbon, Portugal) and/or PCR assay for determination of *S. 1,4,[5],12:i:-*.

† PFGE types are designated by capital letters and include previously described types [5,6] and types described for the first time in this study. The human clinical isolates (n = 4 from four patients) were recovered from three hospitals, and pork products (n = 7) were recovered from six slaughterhouses and one meat production unit.

‡ Antimicrobial susceptibility was evaluated by disc diffusion assay. Variable antibiotic resistance phenotypes and genotypes are presented between brackets. Antibiotic resistance patterns and genes transferred by conjugation are underlined. In two *S. 1,4,[5],12:i:-* isolates, transfer of genes strA-strB and/or bla\_TEM was observed; Some genes were included on class 1 integrons (1,700bp (*dfrA1-aadA1*)) or 2,000bp (*dfrA12-orfF-aadA2*)); Integrons were located on the chromosome in *S. Rissen* (n = 2) and on the IncHI2/ST4 plasmid in *S. 1,4,[5],12:i:-* isolates (n = 2).

§ Screening for genes encoding tolerance to metals were done by PCR [20]. Metal tolerance genes that were not observed in all the isolates are presented between brackets; Metal tolerance genes transferred by conjugation are underlined. All *pcoD + silA* genes were chromosomally located.

resistance to other antibiotics and metals tolerance genes (Table 2). The fact that successful MDR S. 1,4,[5],12::i- and S. Rissen clones have the ability to acquire plasmids carrying the mcr-1 gene is of concern because colistin resistance may contribute to their further expansion, particularly in the pig reservoir. In addition, those strains could act as reservoir of mcr-1-carrying plasmids with a broad host range enhancing colistin resistance transmission for other clinically relevant bacteria sharing the same ecological niche.

Conclusions
This study has evidenced the acquisition of mcr-1-carrying plasmids by two clinically relevant MDR and copper-tolerant clones of S. 1,4,[5],12::i- and S. Rissen, strongly associated with pork food products and which were dominant in the collection studied. The detection of S. 1,4,[5],12::i- from human infections, already in 2011, is also of note, suggesting long-term dissemination of this resistance gene in humans in Portugal. Finally, the detection of mcr-1 in copper-tolerant clones raises questions about the efficacy of recently suggested metal-based interventions (e.g. copper) to reduce the use of colistin and contain mcr-1 dissemination [3].

Acknowledgements
This work was supported by FCT/MEC (Fundação para a Ciência e a Tecnologia / Ministério da Educação e Ciência) through national funds and co-financed by FEDER, under the Partnership Agreement PT2020 [grant number UID/MULTI/04378/2013 – POCI/01/0145/FEDER/007728]. JC is supported by a Ph.D. fellowship from Fundação para a Ciência e a Tecnologia [grant number SFRH/BD/93091/2013].

The authors would like to thank to Linda Cavaco for providing the mcr-1-positive control DNA. We are also very grateful to Jorge Machado (INSA, Lisboa, Portugal) for the Salmonella serotyping.

Conflict of interest
None declared.

Authors’ contributions
JC, LP and PA designed the study and analysed epidemiological, microbiological and molecular data. JC and LC performed the phenotypic and molecular assays. JC and PA wrote the first draft of the manuscript. PA and LP participated in the coordination and concept of the manuscript and revised the final version.
