Atypical clinical presentations associated with group W meningococcal disease (MenW) are well-described and include pneumonia, septic arthritis, endocarditis and epiglottitis/supraglottitis. Following anecdotal reports of teenagers presenting with predominantly gastrointestinal symptoms, we undertook a case review of MenW cases in 15 to 19 year-olds diagnosed in England between July 2015 and January 2016. Of the 15 cases, seven presented with a short history of nausea, vomiting and diarrhoea; five of these seven cases died within 24 hours of presentation to hospital.

The United Kingdom is currently experiencing a national outbreak of group W invasive meningococcal disease (IMD) due to rapid expansion of a single endemic hyper-virulent strain belonging to sequence type (ST) 11 clonal complex (cc) [1]. Group W IMD is associated with atypical clinical presentations, including pneumonia, septic arthritis, endocarditis and epiglottitis/supraglottitis, mainly in older adults [2]. In early 2016, enhanced national surveillance conducted by Public Health England identified two fatal group W IMD cases in teenagers who presented with predominantly gastrointestinal symptoms, prompting a review of all 15 to 19 year-olds diagnosed in England between July 2015 and January 2016. Of the 15 cases, seven presented with a short history of nausea, vomiting and diarrhoea; five of these seven cases died within 24 hours of presentation to hospital.

Seven teenagers (6 females, 1 male) presented predominantly with an acute (24–48 hour) history of gastrointestinal symptoms (nausea, vomiting and/or abdominal pain) together with or followed by diarrhoea in the 24 hours before attending hospital. Two cases were confirmed by blood culture and subsequently characterised as W:2a, a surrogate marker for the hyper-virulent ST-11 cc; the other five were confirmed by PCR. Four of the seven patients had been reviewed either by their general practitioner (GP) or in the Accident and Emergency Department (A and E) on the first day (n=3) or second day (n=1) of illness and sent home with a diagnosis of gastroenteritis. A non-blanching rash at presentation, leading to a consideration of IMD in the differential diagnosis, was identified in only two of the seven teenagers after arrival in hospital. Two died with a presumed diagnosis of ‘gastrointestinal sepsis’ and ‘peritonitis’ soon after presentation to A and E and before they could be transferred to intensive care unit (ICU), while two others died in the ICU within 24 hours of admission. All fatal cases had multi-organ failure. A post-mortem report in one case noted ‘necrotic intestine, shocked lung and systemic sepsis’. Of the two...

A and E: accidents and emergency department; CSF: cerebrospinal fluid; D and V: diarrhoea and vomiting; GP: general practitioner; IMD: invasive meningococcal disease; ICU: intensive care unit; IV: intravenous; N: no; NT: non-typeable; PCR: polymerase chain reaction; Y: yes.

a Days are numbered from the day of symptom onset which is Day 1.
b All culture isolates were subsequently confirmed as W:2a, a surrogate marker for the hyper-virulent sequence type 11 clonal complex, apart from one patient with pneumonia (serotyped as NT/NT/NT).
c Temperature was not reported.
patients who survived, both had short histories of vomiting and diarrhoea for less than 24 hours, went directly to A and E and were seriously unwell at presentation, requiring aggressive resuscitation and ICU admission.

Of the remaining eight cases (3 females, 5 males), seven cases were confirmed by blood (n=6) or cerebrospinal fluid (n=1) culture and six were subsequently characterised as W:2a, a surrogate marker for the hyper-virulent ST-11 cc; a blood culture from one patient with pneumonia was serotyped as NT/NT/NT. Among these eight individuals, two had the more characteristic clinical presentations of septicaemia – fever followed by rapid clinical deterioration (neither had a non-blanching rash) – and one died soon after presenting to A and E. A third teenager presented to A and E within hours of developing symptoms consistent with bacterial meningitis, was treated quickly and recovered without complications.

Four of the remaining five patients had other recognised ‘atypical’ presentations, including septic arthritis and pneumonia. The final case had non-specific symptoms lasting several days and no fever. This individual was managed with intravenous antibiotics in an ambulatory setting and blood cultures subsequently confirmed the diagnosis.

**Discussion**

Laboratory-confirmed group W IMD cases in England have increased from 19 cases in the 2008/09 epidemiological year to 176 cases in 2014/15, and its contribution to total IMD cases increased from 1.7% to 24% of all confirmed cases, respectively [3]. This increase has resulted from rapid expansion of a single endemic hyper-virulent strain belonging to ST 11 cc, which is also responsible for the ongoing group W IMD outbreak in Chile and other South American countries [4]. In August 2015, the United Kingdom (UK) introduced an adolescent MenACWY conjugate vaccination programme targeting 14 to 18 year-olds and new undergraduate university entrants [1].

The increase in group W IMD cases was communicated to clinical and public health colleagues through national briefing notes, peer-reviewed publications and online training materials (www.gov.uk/government/collections/meningococcal-acwy-menacwy-vaccination-programme). These communications emphasised the high case fatality and intensive care admissions, and the well-described atypical clinical presentations – pneumonia, epiglottitis/supraglottitis and septic arthritis – seen in up to a quarter of cases [2].

Although nausea, vomiting and diarrhoea are well-described symptoms of meningococcal disease [5] and are included in most public awareness leaflets and websites (e.g. http://www.mrfpaediatricguide.info/diagnosis.php.html), IMD presentation with primarily gastrointestinal symptoms, whilst previously described, is rare [6,7]. An extensive review of the literature identified only one case report in 1999 in an 80 year-old woman who presented with fever, diarrhoea and abdominal pain; those authors, in turn, had only ascertained three previous cases in young adults in the literature [8]. Consequently, for the cases presented here, IMD was often not considered at first clinical assessment and public health actions, including chemoprophylaxis and vaccination, were, therefore, often delayed and by up to two weeks in one case. There were, however, no secondary cases identified among close contacts.

Interestingly, the unusual gastrointestinal presentation was also reported in the ongoing group W IMD outbreak in Chile, where 14 of 58 group W IMD cases (24%) were initially diagnosed as gastroenteritis and eight of these 14 died [9]. Overall, diarrhoea was the only symptom that was over-represented among the 19 fatal cases (56% vs 27%, p = 0.034), most of whom died within a day of hospitalisation. Early diarrhoea and absence of fever are associated with poor prognosis in IMD, perhaps due to later recognition [10,11].

We are currently following up all confirmed group W IMD cases in England and collecting more detailed clinical data from hospital records for cases presenting with predominantly gastrointestinal symptoms. We are aware of similar presentations in at least three young adults, suggesting that these findings are not confined to teenagers.

**Conclusion**

While atypical presentations such as septic arthritis, pneumonia, epiglottitis/supraglottitis and endocarditis are well-described for the less common meningococcal capsular groups (W and Y), clinical presentation with predominantly gastrointestinal symptoms – and diarrhoea, in particular – appears to be rare and currently associated with the hypervirulent ST-11 group W strain which, in teenagers at least, leads to rapidly progressive, severe disease and high case fatality. It is hoped that the adolescent MenACWY vaccination programme will help to control group W disease in the UK. In the meantime, as this hypervirulent strain is still spreading in South America and has now been reported in other European countries and Australia, it is important that frontline clinicians and public health specialists are aware of this unusual but severe presentation in order to provide appropriate safety net advice) [12], ensure prompt diagnosis and early treatment of cases, and timely chemoprophylaxis with vaccination for close contacts.

**Acknowledgements**

We would like to acknowledge the hard work of the surveillance team at PHE Colindale, the laboratory staff at PHE MRU and the Local Health Protection Teams. In particular we would like to thank Sonia Ribeiro, Kazim Beebeejaun, Steve Gray and Jay Lucidarme.
